Plaintiff,

v.

Civil Action No. _____

HON. JOHN J. DOLL)
Under Secretary of Commerce for Intellectual)
Property and Director of the United States)
Patent and Trademark Office)
Madison Building)
600 Dulany Street)
Alexandria, Virginia 22314)

COMPLAINT

Plaintiff Institut National Des Sciences Appliquees (INSA) for its complaint
against Defendant the Honorable John J. Doll, state as follows:

1. This is an action by the owners of United States Patent No. 7,439,049 ("the '049 patent") seeking review of inaccurate and erroneous Patent Term Adjustment ("PTA") calculations made by the United States Patent & Trademark Office ("USPTO"). Specifically, this is an action by Plaintiffs under 35 U.S.C. § 154(b)(4)(A) seeking a judgment that the patent term adjustment of

301 days calculated by the USPTO for the '049 patent should be corrected to 755 days.

2. This action arises under 35 U.S.C. § 154 and the Administrative Procedure Act, 5 U.S.C. §§ 701-706.

I. THE PARTIES

3. Plaintiff Institut National Des Sciences Appliquees is a company operating under the laws of France. Institut National Des Sciences Appliquees is located at 135 Avenue De Rangueil 31077 Toulouse, France.
4. Defendant John J. Doll is the Under Secretary of Commerce for Intellectual Property and Director of the United States Patent and Trademark Office. Defendant is sued in his official capacity.

II. JURISDICTION AND VENUE

5. This Court has jurisdiction over this action and is authorized to issue the requested relief to Plaintiff pursuant to 28 U.S.C. §§ 1331, 1338(a) and 1361; 35 U.S.C. § 154(b)(4)(A) and 5 U.S.C. §§ 701-706.
6. Venue is proper in this district pursuant to 35 U.S.C. § 154(b)(4)(A).
7. This Complaint is being timely filed in accordance with 35 U.S.C. §154(b)(4)(A).

III. BACKGROUND

8. The inventors of the '049 patent are Sophi Anne Michèle Bozonnet, Magali

Martine Claude Remaud-Simeon, René-Marc Lucien Willemot, and Pierre Emmanuel Frédéric Monsan.

9. The '049 patent granted on October 21, 2008, based on patent application number 10/509,027, filed September 27, 2004. The '049 patent is attached hereto as Exhibit A.
10. Plaintiff Institut National Des Sciences Appliquees are the assignees of the '049 patent, as evidenced by the Assignment recorded in the USPTO at Reel/Frame 018179/0440, and are the real parties in interest in this case.
11. When the USPTO issued the '049 patent on October 21, 2008, it erroneously calculated the entitled PTA for the '049 patent as 301 days. Had the USPTO calculated the entitled PTA properly, the '049 patent would be entitled to 755 days of PTA.
12. The errors in the USPTO's PTA calculations are detailed in a recent order from the U.S. District Court for the District of Columbia in an action titled *Wyeth v. Dudas*, Civil Action No. 07-1492 (D.D.C. Sept. 30, 2008) where the Court granted summary judgment against the USPTO, holding that the USPTO's PTA calculation methodology was erroneous as a matter of law and inconsistent with the Patent Statute. The *Wyeth v. Dudas* opinion is attached as Exhibit B.
13. The correct PTA methodology identified in the prior *Wyeth v. Dudas* action governs the USPTO's calculation of PTA for Plaintiff's '049 patent.

IV. COUNT I: U.S. PATENT NO. 7,439,049

14. Plaintiff incorporates by reference the allegations in paragraphs 1-14 above, as if fully set forth herein.
15. During prosecution of the '049 patent, the patent owners accrued 429 days of PTA under 35 USC § 154(b)(1)(A), and accrued 390 days of PTA under 35 USC 154(b)(1)(B).
16. Under the USPTO's interpretation of 35 USC § 154, all PTA accrued under 35 U.S.C. § 154(b)(1)(A) and all PTA accrued under 35 USC § 154(b)(1)(B) inherently overlaps and, thus, it has been the USPTO position that a patent holder is only eligible for the larger of these two amounts of PTA. For the '049 patent, the USPTO erroneously limited the PTA for the '049 patent to 301 days (see calculation in paragraph 19, below), as shown on the face of the '049 patent.
17. In view of a recent decision from this Court (*Wyeth v. Dudas*, Civil Action No. 071492 (JR)), all days on which 35 USC 154(b)(1)(A) or 35 USC 154(b)(1)(B) apply should accrue PTA for the '049 patent.
18. Under the interpretation of this Court (*Wyeth v. Dudas*, Civil Action No. 07-1492 (JR)), each day from the day after November 27, 2005 (14 months from the '049 patent application filing date) through to the grant date on October 21, 2008, qualifies for PTA under 35 U.S.C. § 154(b)(1)(A), (411 days, see calculation of paragraph 20, below) and each day from the day after September

27, 2007 (three years from the filing date) through to the grant date on October 21, 2008 qualifies for PTA under 35 U.S.C. § 154(b)(1)(B) (390 days) for a total of 801 days.

19. In calculating the time accrued under 35 USC 154 (b)(1)(B) the Plaintiff disagrees with the USPTO's holding of a total USPTO prosecution delay of 301 days under 35 USC 154(b)(2)(B). The Plaintiff believes that the total USPTO prosecution delay should be 383 days under 35 USC 154(b)(2)(B) because the USPTO incorrectly deducted 82 days due to the filing of a "Letter" on May 30, 2008. The "Letter" of May 30, 2008 explained to the Examiner that the initial Information Disclosure Statement (IDS) filed on September 27, 2004 was in compliance with 37 CFR § 1.98. The USPTO incorrectly considered the "Letter", a Supplemental Reply to applicant's original request regarding the IDS that was filed April 10, 2008. However, the "Letter" was as noted above and was submitted to correct an error by the Examiner. Thus there should have been no 82 day deduction made to the accrued PTA of 390 days

20. Plaintiff concede a two day delay under 35 USC 154(b)(1)(B) for the response filed December 26, 2007 to the Office Action issued September 24, 2007, as well as a 44 day delay for paper filed after Allowance on May 23, 2008. Plaintiff further concedes an overlap of 18 days of credits accrued under 35 USC 154(b)(1)(A). Thus the total PTA should be:

- a. $429 \text{ days credit under 35 USC 154(b)(1)(A)} - 18 \text{ days overlapping} = 411$
days of PTA under 35 USC 154(b)(1)(A).

- b. 390 days credit under 35 USC 154(b)(1)(B) – 46 days delay by applicant = 344 days of PTA under 35 USC 154(b)(1)(B).
- c. Thus the total PTA is 411 days under 35 USC 154(b)(1)(A) + 344 days under 35 USC(b)(1)(B) = 755 days

21. Under the USPTO's interpretation, the USPTO had calculated an erroneous PTA of $429 - 128 = 301$ days.

21. The Plaintiff's imposition of only 301 days of PTA for the '049 patent is arbitrary, capricious, and abuse of discretion, or otherwise not in accordance with law and in excess of statutory jurisdiction, authority or limitation.

22. It is accordingly believed that the overall PTA accrued by the Plaintiff is **755 days**, and the patent holder accordingly requests $755 - 301 = 454$ **ADDITIONAL days** of PTA.

WHEREFORE, Plaintiffs respectfully pray that this Court:

A. Issue an Order changing the period of PTA for the '049 patent term from 301 days to 755 days and requiring Plaintiff to alter the terms of the '049 patent to reflect the 755 days of actual PTA due the '049 patent.

B. Grant such other and further relief as the nature of the case may admit or require and as may be just and equitable.

Dated: April 6, 2009

Respectfully submitted,

Quentin R. Corrie (DC Bar No. 224469)

(57) **ABSTRACT**

The invention relates to an isolated polypeptide with an glycosyl transferase enzymatic activity for producing dextrans with α (1 \rightarrow 2) sidechains, comprising at least one region for bonding to glucan and a catalytically active region situated beyond the region bonding to glucan. The invention further relates to polynucleotides coding for said enzymes and vectors containing the same.

**NUCLEIC ACID MOLECULES CODING FOR
A DEXTRAN-SACCHARASE CATALYSING
THE SYNTHESIS OF DEXTRAN WITH α 1,2
OSIDIC SIDECHAINS**

The present invention relates to the field of glycotechnology, more particularly to the synthesis of oligosaccharides or oligosides with a prebiotic, therapeutic or diagnostic effect.

The present invention pertains to nucleic acid molecules encoding an enzyme having a glycosyltransferase activity catalyzing the synthesis of dextrans or oligosides carrying α (1 \rightarrow 2) osidic type linkages.

The invention also pertains to enzymes synthesized by the nucleic acids of the invention, and to their expression systems in prokaryotic or eukaryotic cells. Finally, they pertain to the use of said enzymes in the production of oligosaccharides in foodstuffs, or as an active principle in therapeutic and/or cosmetic products.

Oligosides and heterooligosides act as recognition and effector signals in both animals and plants (as oligosaccharines) by specifically binding to lectins, glycosyltransferases, glycosidases, adhesion molecules etc. The antigenic determinants of blood groups are osidics and our defense against many pathogenic bacteria is directed against osidic structures of the bacterial envelope. Further, one of the major reasons for xenograft rejection is the existence of osidic structures belonging to each species. Such properties, and the knowledge acquired in recent years regarding glycosyltransferases and lectins, contribute to making certain oligosides the candidates of choice for therapeutic or prophylactic treatment of disorders linked to the microbiological equilibrium of various organs such as the intestine or skin. As an example, oligosides constitute an interesting alternative to the use of micro-organisms and antibiotics in regulating the composition of intestinal flora (prebiotic effect). Certain oligosides can be considered to be "soluble fiber" when they are not metabolized by human and animal digestive enzymes; on reaching the colon, they interact with the microbial flora and specifically affect the growth and adhesion of certain species. If they are incorporated into food in low doses (less than 1%), certain osidic molecules improve health and stimulate weight gain in animals.

A review of different glycosyltransferases, their structure and their activity, has been carried out by Vincent Monchois et al (1). Briefly:

a) it appears that the structure of the glycosyltransferases and/or dextranases studied is highly conserved and is constituted, starting from the amino part of the protein, by a signal sequence, a variable domain, a catalytic domain and a glucan binding domain.

b) glucooligosides (GOS) can be synthesized by glycosyltransferases such as dextranases from cheaper substrates such as saccharose and in the presence of a glucose accepting sugar. Other substrates such as α -D-fluoroglucose, para-nitrophenyl- α -D-glucopyranoside, α -D-glucopyranoside- α -D-sorbofuranoside or 4-O- α -D-galactopyranosylsucrose can also be used.

Starting from the substrate, such enzymes catalyze the transfer of glucose units onto acceptor molecules. In the presence of a glucose acceptor such as maltose or isomaltose, glycosyltransferases catalyze the synthesis of low molecular weight oligosaccharides primarily comprising chains with 3 to 7 glucoses, in accordance with the reaction:

2

In such cases, enzymes generally have a specificity for the synthesis of osidic bonds in accordance with that forming the donor polymer.

In contrast, in the absence of an acceptor, the enzyme synthesizes high molecular weight dextran type glucans by successive transfer of α -D-glucopyranosyl units from saccharose in accordance with the reaction:

c) The structures and function of glucans or oligosides synthesized by glycosyltransferases depends on the producing bacterial strain.

Throughout the present text, the generic term "glycosyltransferases" is used to designate the different enzymes capable of catalyzing the synthesis of glucose polymers from saccharose. They are generally produced by bacterial strains of the *Leuconostoc*, *Lactococcus*, *Streptococcus* or *Neisseria* type. The size and structure of the glucans produced depends on the producing strain.

The glucose units are coupled by α (1 \rightarrow 6) osidic bonds as in dextran, by α (1 \rightarrow 3) bonds as in the case of mutane, or by alternations of the two types (alternane).

Similarly, the existence and nature of the linkages, their length and position varies depending on the origin of the producing strain.

Glycosyltransferases producing glucans or GOSs containing at least 50% α (1 \rightarrow 6) bonds are termed dextranases. GOSs synthesized by said enzymes may carry α (1 \rightarrow 2), α (1 \rightarrow 3) and/or α (1 \rightarrow 4) linkages. Said dextranases are produced by *Leuconostoc mesenteroides* type bacteria.

d) The dextranase from *L. mesenteroides* NRRL B-1299 can produce a highly branched dextran the majority of linkages of which are of the α (1 \rightarrow 2) type. Used in the presence of saccharose and maltose, a glucose acceptor molecule, it results in the formation of GOS some of which have a α (1 \rightarrow 2) bond at their non-reducing end and others of which have α (1 \rightarrow 2) linkages on intermediate residues between the ends. For this reason, they resist degradation by enzymes (hydrolases) of the upper digestive tract in man and animals, and are only degraded by bacterial genres that are capable of fermenting, such as *Bacteroides* and *Bifidobacterium*, considered to be beneficial to the host organism.

An identical phenomenon occurs in the skin, allowing cosmetic applications to be envisaged, since a lack of equilibrium of the cutaneous microbial flora is the root of numerous cosmetic and dermatological problems. For these reasons, they are designated "GOS of interest" in the present text.

Throughout the text, polysaccharides synthesized by the glycosyltransferases of the invention are either high molecular weight dextrans when the reaction is carried out without a glucose acceptor, or oligosides when the reaction is carried out in the presence of a glucose acceptor such as maltose or isomaltose without this necessarily being specified. The functionality of the enzyme is characterized by the nature of the glucose-glucose bonds, [α (1 \rightarrow 6), α (1 \rightarrow 2)] or others, and not by the molecular weight of the polysaccharide that is synthesized.

dextranases from *L. mesenteroides* already have a number of applications in industry, and in particular those from the NRRL B-1299 strain for which a method for synthesizing GOSs having α (1 \rightarrow 2) linkages has been described in European patent EP-B1-0 325 872.

Marguerite Dols et al (2) showed that the GOS produced by dextranases from that strain are in fact a mixture of at least three similar families of molecules differing by the number and position of the α (1 \rightarrow 2) type linkages, which

US 7,439,049 B2

3

leads to the hypothesis that different glycosyltransferase type enzymatic activities exist in that bacterial strain.

Because of the industrial interest pertaining to GOSs with $\alpha(1\rightarrow2)$ linkages as summarized above in the field of prebiotic foodstuffs, in cosmetics or in pharmaceuticals, the present invention aims to isolate and characterize a particular enzyme from among those produced by *L. mesenteroides* NRRL B-1299 which more particularly would be involved in the synthesis of oligosides having $\alpha(1\rightarrow2)$ linkages. The identification and characterization of such an enzyme have the advantage firstly of providing a uniform, reproducible method for producing GOSs of interest and secondly of identifying the essential characteristics of the producer enzyme for said GOSs of interest in order, if appropriate, to improve the performance of the products of the enzymatic reaction as a function of the envisaged use.

The technical problem underlying the present invention is thus to provide an enzyme and hence isolated nucleic acids encoding said enzyme to allow the improved production of GOS having $\alpha(1\rightarrow2)$ linkages.

The present invention provides a technical solution to the various questions mentioned above by providing a novel dextranucrase, termed DSR-E, encoded by a gene endowed with a novel and unexpected structure (*dsrE*) capable of catalyzing the synthesis of glucans or oligosaccharides containing $\alpha(1\rightarrow2)$ linkages.

Between the date of filing of the priority document, French patent number 0103631 in which the dextranucrase of the invention was termed DSR-D, and that of the present application, another dextranucrase, different from the enzyme of the invention, was described and also termed DSR-D. For this reason, in the present patent application, the dextranucrase described, claimed and shown in FIG. 1b) is no longer designated DSR-D as in the priority document, but is termed DSR-E. In fact, the DSR-D dextranucrases in said priority document and DSR-E are completely identical.

The term "novel and unexpected structure" means that the organization of the protein differs from that of all other glycosyltransferases described until now (1) with a catalytic domain located upstream of a glucan binding domain, the latter constituting the carboxylic portion of the protein.

The present invention thus concerns an isolated polypeptide having an enzymatic glycosyltransferase activity capable of forming dextrans having $\alpha(1\rightarrow2)$ linkages, characterized in that it comprises at least one glucan binding domain and a catalytic activity domain located downstream of the glucan binding domain. The term "located downstream" means the fact that the amine portion of the sequence with catalytic activity or catalytic domain is proximal to the carboxylic portion of the glucan binding domain. These two domains can be immediately contiguous or, in contrast, they may be separated by a variable domain.

The glycosyltransferase of the invention preferably comprises a signal peptide.

In one implementation of the invention, the glycosyltransferase comprises two catalytic domains located either side of the glucan binding domain.

The presence of a domain with catalytic activity in the carboxylic portion of the enzyme is an essential characteristic of the latter in its capacity to form osidic $\alpha(1\rightarrow2)$ bonds. In fact, as will be shown in the experiments described below, deletion of this domain in an enzyme having at least two catalytic domains results in the production of glucans or oligosides essentially having $\alpha(1\rightarrow6)$ type osidic bonds and free of $\alpha(1\rightarrow2)$ type bonds.

4

More precisely, the catalytic domain, as long as it is located downstream of a glucan binding domain, allows the synthesis of oligosides containing $\alpha(1\rightarrow2)$ bonds.

Further, the experiments described below demonstrate that the specificity of the dextranucrase DSR-E function, namely its capacity to catalyze the formation of $\alpha(1\rightarrow2)$ osidic bonds, can be attributed not to the concomitant presence of two catalytic domains but rather to the concatenation of a glucan binding domain and a catalytic domain, and more particularly the CD2 catalytic domain.

A comparative analysis of the different glycosyltransferases including dextranucrases has demonstrated a very high degree of conservation of their catalytic domain.

The catalytic domain located in the carboxy-terminal portion of the glycosyltransferase of the invention has a sequence having at least 44% identity and 55% similarity with the catalytic domains of the other analyzed glycosyltransferases. In particular, the catalytic domain in the carboxylic portion of the glycosyltransferase of the invention has at least 65% identity and at least 80% similarity with the SEQ ID No: 1, the catalytic triad Asp/Glu/Asp in respective positions 230/268/342 being conserved.

Throughout the text, the term "X %" similarity" with respect to a reference sequence means that X % of the amino acids are identical or modified by conservative substitution as defined in the ClustalW amino acid alignment software (<http://bioweb.pasteur.fr/docs/doc-gensoft/clustalw/>) and that (100-X)% can be deleted, substituted by other amino acids, or that (100-X)% can be added to the reference sequence. A particular primary structure of the enzyme of the invention is shown in SEQ ID No: 2 which represent a sequence of 2835 amino acids of a dextranucrase of *L. mesenteroides* NRRL B-1299.

This dextranucrase, denoted DSR-E, like most glycosyltransferases and dextranucrases, has a signal sequence, a variable domain of low conservation, a highly conserved catalytic domain (CD1), a glucan binding domain (GBD) and a second catalytic domain (CD2) in the carboxylic portion of the protein. DSR-E is the first glycosyltransferase analyzed and has two catalytic domains, in the configuration shown in FIG. 1b). It is also the first glycosyltransferase the catalytic domain of which is located in the carboxylic portion of the protein.

FIG. 1b) also shows that the glucan binding domain is substantially longer than that described above for known dextranucrases; thus, a further characteristic of the enzymes of the invention is the size of this domain which is over 500 amino acids.

A comparison and analysis of the DSR-E sequence with the sequences of the glycosyltransferases or dextranucrases that have already been described (1), and the means used to this end are indicated in Example 2 detailed below. It clearly shows that while the existence of two catalytic domains substantially differentiates DSR-E from other enzymes, in contrast the sequences of said domains are substantially conserved. In particular, the amino acids necessary for catalytic activity are conserved in the second catalytic domain, namely the triad Asp/Glu/Asp located in respective positions 2210/2248/2322 of SEQ ID No: 2.

Thus, the invention also concerns any isolated polypeptide having a catalytic glycosyltransferase activity that is capable of forming dextrans or oligosaccharides having $\alpha(1\rightarrow2)$ linkages as obtained by modification, substitution, insertion or deletion of amino acid sequences but comprising sequences having at least 80% and preferably at least 90% similarity with the following sequences of SEQ ID No: 2:

US 7,439,049 B2

5

423-439	2120-2138
478-501	2161-2184
519-539	2202-2214
560-571	2243-2250
631-645	2315-2322
1014-1021	2689-2696

Preferably, finally, a polypeptide with catalytic activity of the invention contains the following amino acids:

- W in positions 425 and 2122;
- E in positions 430, 565 and 2127, 2248;
- D in positions 487, 489, 527, 638, 2170, 2172, 2210 and 2322;
- H in position 637 and 2321;
- Q in position 1019 and 2694.

The polypeptides with glycosyltransferase activity that can form osidic $\alpha(1\rightarrow2)$ bonds can be in the isolated form or, in contrast, integrated into a larger protein such as a fusion protein. It may be advantageous to include sequences having another function, such as a specific tag sequence of a ligand that can facilitate purification. These tag sequences can be of the following types: GST (glutathione-S-transferase), intein-CBD (chitin-binding domain) (sold by New England Biolabs, <http://www.neb.com>), MBD (maltose binding domain), polypeptides containing contiguous histidine residues that can facilitate purification of the polypeptide with which it is fused. The skilled person could design any other fusion protein that could associate the function of the DSR-E of the invention with another function, a non limiting example being a sequence increasing the stability of the enzyme produced by expression in a recombinant host or a sequence that can increase the specificity or efficacy of action of said enzyme, or a sequence aimed at associating another connected enzymatic activity.

Such fusion proteins also fall within the scope of the invention provided that they contain the CD2 domain of the glucan binding site. In the same manner, fragments of SEQ ID No: 2, comprising at least SEQ ID No: 1 and the glucan binding domain, alone or integrated into a larger polypeptide forms part of the invention, as long as the enzymatic activity of the dextranucrase is conserved.

Variations of the polypeptide sequences defined above also form part of the invention. In addition to the polypeptides obtained by conservative substitution of the amino acids defined above, the variations include polypeptides the enzymatic activity of which is improved, for example by directed or random mutagenesis, by DNA shuffling, or by duplication of the CD2 catalytic domain.

The particular structure of this enzyme identified in the present invention results from a process comprising:

- a) identifying and isolating dextranucrase from *L. mesenteroides* catalyzing the production of GOSs of interest carrying $\alpha(1\rightarrow2)$ linkages;
- b) sequencing the enzyme fragments;
- c) synthesizing amplification primers that can amplify the gene corresponding to the producing strain or fragments thereof;
- d) sequencing the amplified fragments;
- e) cloning in specific vectors and their expression in appropriate hosts.

The features of the method employed are given in detail in the experimental section below. The first step consists of separating the proteins by polyacrylamide gel electrophoresis and identifying bands having a dextranucrase activity by an in situ enzymatic reaction in the presence of substrate and

6

acceptor. The nature of the GOSs synthesized is then identified for each band by HPLC analysis using the methods described in (1). The retention time for the oligosides in HPLC depends on the nature and organization of their osidic bonds. In particular, it is possible to distinguish between those constituted by residues having $\alpha(1\rightarrow6)$ bonds, having $\alpha(1\rightarrow6)$ bonds with a $\alpha(1\rightarrow2)$ linkage at the nonreducing end of the molecule, and the desired compounds having a linear $\alpha(1\rightarrow6)$ chain with $\alpha(1\rightarrow2)$ linkages.

The inventors therefore isolated and identified dextranucrase from *L. mesenteroides* NRRL B-1299 producing GOSs of interest.

A reverse engineering process carried out in steps b) to e) above then provide the nucleotide sequence encoding the enzyme, allowing industrial scale production and, if appropriate, allowing it to be modified, improving its performance using techniques that are available to the skilled person. As an example, directed or random mutagenesis or DNA shuffling can be cited (3).

The invention also pertains to an isolated nucleic acid molecule encoding an enzyme with glycosyltransferase activity that can form dextrans or oligosides having $\alpha(1\rightarrow2)$ linkages and comprising at least one sequence encoding a glucan binding domain, and at least one nucleotide sequence encoding a catalytic domain located on the 3' side of the foregoing, said sequence encoding a catalytic domain having at least 50% and preferably at least 70% similarity with SEQ ID No: 3.

The term "similarity" means that for the same reading frame, a given triplet is translated by the same amino acid. Thus, this term includes modifications to bases resulting in degeneracy of the genetic code.

The percentage similarity is determined by comparing a given sequence with the reference sequence. When they have different lengths, the percentage similarity is based on the percentage of nucleotides in the shortest sequence which are similar to those in the longest sequence.

The degree of similarity can be conventionally determined using software such as ClustalW (Thompson et al, Nucleic Acid Research (1994), 22: 4673-4680) distributed by Julie Thompson (Thompson@EMBL-Heidelberg.de) and Toby Gibson (Gibson@EMBL-Heidelberg.de) at the European Molecular Biology Laboratory, Meyerhofstrasse 1, D-69117, Heidelberg, Germany. ClustalW can also be downloaded from a number of websites including IGBMC (Institut de Génétique et de Biologie Moléculaire et Cellulaire, B P 163, 67404 Illkirch Cedex, France; <ftp://ftp-igbmc.u-strabg.fr/pub/>) and EBI (<ftp://ftp.ebi.ac.uk/pub/software/>) and all sites linking to the Bioinformatics Institute (Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SD, UK).

The isolated nucleic acids of the invention can in particular comprise other sequences intended to improve the expression and/or activity of the enzyme produced.

As an example, they can be:

- sequences encoding a signal sequence for their secretion;
- duplication of the sequence encoding the CD2 catalytic domain.

Preferably, an isolated nucleic acid of the invention comprises:

- a) two sequences encoding catalytic domains having at least 50%, preferably at least 80% similarity with SEQ ID No: 3;
- b) a sequence enclosing the glucan binding domain, the latter preferably being located between the two sequences in a).

US 7,439,049 B2

7

A nucleic acid of the invention can also comprise:
a promoter suitable for its expression in a selected host cell;
a sequence encoding a signal peptide; and/or
one or more variable sequences;
said sequence or sequences all being located in the 5' portion of sequences encoding the catalytic domain(s).

A more particular example of an isolated nucleic acid of the invention comprises:

- a) SEQ ID No: 4;
- b) a sequence having at least 80% similarity with SEQ ID No: 4; or
- c) the complementary strand to sequence a) or b); or
- d) a sequence hybridizing a), b) or c).

The hybridization in d) is carried out under standard conditions, and preferably under stringent conditions. The term "hybridization under stringent conditions" means that there is at least 80% sequence identity with the sequence which is to be hybridized, preferably an identity of at least 90% of the sequence which is to be hybridized, under conditions which are, for example, described in Sambrook and Russel (3rd edition, 2001, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y.).

The invention also concerns a gene encoding a dextranucrase that can form at least 15% $\alpha(1 \rightarrow 2)$ linkages. In addition to the encoding sequence, the gene comprises sequences that allow transcription initiation and sequences that allow attachment of messenger RNA to the ribosome (RBS). SEQ ID No: 5 represents a gene structure as isolated from *L. mesenteroides* NRRL B-1299.

The nucleotides upstream of the translation initiation ATG are numbered 1 to 232.

The existence of a RBS sequence can be identified between nucleotides 218 and 223 as well as the consensus sequences -35 and -10 located between nucleotides 82 and 86 (TTGAA) on the one hand and 100 and 105 (ATAAAT) on the other hand.

Any nucleic acid sequence that can be hybridized with DNA of SEQ ID No: 4 or its complementary strand is capable of encoding an enzyme having the properties and characteristics of the enzyme of the invention. This applies to natural sequences existing in micro-organisms other than *L. mesenteroides* NRRL B-1299 and isolated from gene libraries of micro-organisms, and to those prepared by genetic engineering or by chemical synthesis.

In particular, the sequences upstream of the translation initiation ATG and necessary for expression of the protein can advantageously be substituted by transcription initiation and/or ribosome binding sequences suitable for the expression system selected for the coding sequence.

A nucleic acid sequence that is capable of hybridizing under stringent conditions with the isolated nucleic acid of the invention also comprises fragments, derivatives or allele variations of the nucleic acid sequence of the invention which encodes a protein having the enzymatic activity described above. Thus, the fragments are defined as fragments of nucleic acid molecules that are sufficiently long to encode a protein that has conserved its enzymatic activity. This also encompasses fragments that are free of the sequence encoding the signal peptide responsible for protein secretion.

The term "derivative" means a sequence that is different from the original sequence in one or more positions but which has a high degree of similarity with said sequences. In this context, "similarity" means at least 80% identity of the nucleotides, preferably at least 90% identity with the original sequence. The modifications in this case are deletions, substitutions, insertions or recombinations provided that the

8

enzyme encoded by these homologous sequences has the enzymatic activity of the polypeptides of the invention.

The nucleic acid sequences of the invention as described above and qualified by derivatives of said molecules as defined above are generally variations exerting the same biological function. Said variations can be natural variations, in particular those observed from one species to another and resulting in interspecies variability or, in contrast, those introduced via directed or random mutagenesis or by DNA shuffling.

Similarly, the invention encompasses isolated nucleic acids encoding a glycosyltransferase that can catalyze the synthesis of dextran or oligosaccharide carrying at least 20% and preferably at least 30% type $\alpha(1 \rightarrow 2)$ linkages obtained by DNA shuffling and comprising:

- a step for random modification of one of the sequences defined above and in particular SEQ ID Nos: 3 and 4 and establishing the variations;
- a step for expressing a host housing a variation from said modified sequences in a suitable host cell;
- a step for screening hosts expressing an enzyme that can form more than 20% and preferably more than 30% $\alpha(1 \rightarrow 2)$ bonds on a suitable substrate and a step for isolating the improved gene or genes.

An isolated nucleic acid of the invention can also comprise:

- a) a sequence containing at least 80% similarity with the sequence encoding a dextranucrase expressed by the plasmid pCR-T7-dsrE in *E. coli* deposited at the CNCM on 15th Mar. 2001 with accession number I-2649 (*E. coli* JM 109 [pCR-T7-dsrD]), or
- b) a complementary sequence of the sequence in a).

The denomination of the strain transformed by the recombinant plasmid pCR-T7-dsrE deposited at the CNCM is that indicated above in brackets. This does not affect the change in the denomination of the gene carried out following deposition of said strain for the reasons given above.

The invention also concerns nucleic acid fragments as defined above, which are hybridizable with SEQ ID No: 4 and can be used as hybridization probes for detecting sequences encoding the enzymes of the invention. Said fragments can be prepared using any technique known to the skilled person.

In addition to hybridization probes, amplification primers also form part of the invention. Said primers are fragments which are hybridizable with SEQ ID No: 4 or with its complementary strand and which allow amplification of specific sequences encoding dextranucleases present in a prokaryotic or eukaryotic animal or plant organism.

The use of said amplification primers allows the use of a method for identifying the possible existence of a gene encoding an enzyme that can catalyze synthesis of GOS with $\alpha(1 \rightarrow 2)$ linkages in said organism, said method also forming part of the invention.

The invention also concerns expression vectors comprising a nucleic acid as described above under the control of a sequence allowing its expression and preferably its excretion in prokaryotic or eukaryotic cells. The term "prokaryotic cells" preferably denotes bacteria selected from a group comprising *E. coli*, *Lactococcus*, *Bacillus* and *Leuconostoc*. The term "eukaryotic cells" preferably means eukaryotes selected from a group containing yeasts, fungi and plants.

The vector comprises a promoter suitable for expression of the isolated nucleic acid of the invention in the selected expression system. As an example, the T7 bacteriophage promoter could advantageously be selected for expression in *E. coli*.

The invention also concerns host cells, prokaryotic or eukaryotic, transformed by a nucleic acid of the invention,

US 7,439,049 B2

9

preferably comprised in an expression vector carrying a promoter, adapted for expression in the selected host cells. The transformed cells are selected from Gram- bacteria such as *E. coli*, or from Gram+ bacteria such as *Lactococcus*, *Bacillus*, *Leuconostoc*, or from eukaryotes in a group comprising yeasts, fungi and plants.

One particular example of a cell transformed in accordance with the invention is the *E. coli* strain harboring a plasmid termed pCR-T7-dsrE carrying the SEQ ID No: 4 under the control of the T7 bacteriophage promoter deposited at the CNCM on 15th Mar. 2001 under accession number I-2649.

The present invention also concerns a method for producing a glycosyltransferase that can form dextrans or oligosides having at least 15% and preferably at least 20% of type $\alpha(1\rightarrow2)$ osidic linkages and comprising:

- a) inserting a nucleic acid or a vector as defined above into a host cell that can express and preferably secrete the glycosyltransferase;
- b) characterizing the enzymatic activity being investigated using any of the methods accessible to the skilled person;
- c) purifying the enzyme from a cell extract.

The term "method for characterizing enzymatic activity known to the skilled person" means the methods described in the literature, for example in reference (2), and novel methods that may be developed to allow identification and discrimination of glucooligosaccharides having the desired degree of linkages.

In fact, it concerns any screening method that can identify the presence of $\alpha(1\rightarrow2)$ linkages in a GOS.

Examples are:

- HPLC in which GOS migration varies as a function of the nature and position of the linkages, in particular those containing the $\alpha(1\rightarrow2)$ bond at the reducing end and those containing this bond on the penultimate glucose; and/or
- nuclear magnetic resonance (NMR);
- the existence of a positive reaction with specific monoclonal antibodies of $\alpha(1\rightarrow2)$ bonds on the reducing end and/or specific monoclonal antibodies of $\alpha(1\rightarrow2)$ bonds on the penultimate glucose of the GOS.

The invention also concerns a method for obtaining a glycosyltransferase that can have oligosides or dextrans having a percentage of $\alpha(1\rightarrow2)$ linkages of more than 15% and preferably more than 30% of the totality of the osidic bonds and comprising a step for modifying SEQ ID No: 4 by addition, deletion or mutation provided that:

- the reading frame is not modified; and
- the following amino acids are conserved after translation:
 - W in positions 425 or 2122, encoded by the TGG triplet in positions 1273 and 6364;
 - E in positions 430, 565, 2127 and 2248, encoded by GAA triplets in positions 1288, 1693, 6379 and 6742 respectively;
 - D in positions 487, 489, 527, 638, 2170 and 2210, encoded by GAT triplets in positions 1459, 1465, 1579, 1912, 6508 and 6628 respectively;
 - D in positions 2172 and 2322 encoded by GAT triplets in positions 6514 and 6964;
 - H in position 637 and 2321, respectively encoded by the CAT triplet in position 1909 and CAC in position 6961;
 - Q in positions 1019 and 2694, respectively encoded by triplets CAA (position 3055) and CAG (position 8080).

A method for producing a glycosyltransferase according to the invention having the same characteristics as above can also comprise:

10

- a step for randomly modifying SEQ ID No: 4 and establishing a library of variations;
- a step for expressing a host housing a variation from said modified sequences in a suitable host cell;
- a step for screening hosts expressing an enzyme that can form more than 15% and preferably more than 30% of $\alpha(1\rightarrow2)$ bonds on a suitable substrate;
- and a step for isolating the improved gene or genes.

In a further implementation of the invention, the method consists of modifying SEQ ID No: 3 by duplicating all or part of the CD2 catalytic domain.

It should be understood that the methods above are not only aimed at obtaining a glycosyltransferase that can form oligosides having a constant and reproducible percentage of $\alpha(1\rightarrow2)$ linkages of more than 15% of the total linkages, but also to improve the degree of $\alpha(1\rightarrow2)$ linkages with the aim of modifying the properties of the oligosides obtained to improve their dietetic properties or their capacity to maintain or re-establish bacterial flora associated with certain organs of the human or animal body.

Finally, the present invention concerns glycosyltransferases that can be obtained by a method as defined above and which can form at least 15% and preferably at least 30% of type $\alpha(1\rightarrow2)$ osidic linkages in glucooligosaccharides.

Finally, the invention pertains to the use of glycosyltransferases of the invention as well as those that can be obtained by the methods mentioned above, in the production of a composition with a pre-biotic effect or in the manufacture of a dermatological, cosmetic or pharmaceutical composition.

Non-limiting examples that can be cited are the improvement in intestinal transit in animals and in man, an improvement in calcium and/or magnesium assimilation and of minerals in general, preventing cancer of the colon and prevention or treatment of skin affections such as acne, dandruff or body odor.

The advantage of the polypeptides and nucleic acids encoding said polypeptides of the invention is not only in improvements in terms of quality, yield, reproducibility and cost of glycosyltransferases that can form oligosaccharides with type $\alpha(1\rightarrow2)$ osidic linkages, but also in producing novel enzymes the functionality of which is improved.

The figures, examples and detailed description below provide non-limiting illustrations of the particular characteristics and functionalities of polypeptides with enzymatic activity and sequences encoding them. In particular, they can illustrate more precisely the specificity of the catalytic domain present in the carboxylic portion of the enzyme of the invention and its potential evolution to obtain improved enzymes.

KEY TO FIGURES

FIG. 1: Structure of native glycosyltransferases and derived recombinant proteins: FIG. 1a) shows the structure of glycosyltransferases and dextransucrases described in the literature (1). PS: signal peptide; ZV: variable zone; CD: catalytic domain; GBD: glucan binding domain. FIG. 1b) shows the structure of the glycosyltransferase of the invention. FIGS. 1c) to 1f) show different constructions comprising deletions in comparison with native DSR-E protein. $\Delta(PS)$ corresponds to the control constituted by the entire form cloned into the pBAD-TOPO thiofusion system (Invitrogen).

FIG. 2: Diagrammatic summary of the method for cloning the nucleotide sequence encoding a glycosyltransferase of the invention using a genome library by using a PCR probe described in Table 1 and a HindIII/EcoRV probe respectively.

FIG. 3: Comparison of the signal sequences of different glycosyltransferases of *L. mesenteroides* (residues 1-40 of

SEQ ID NO: 2). The conserved amino acids are shown in bold. DSR-B: *L. mesenteroides* NRRLB-1299 (4) (SEQ ID NO: 45); DSR-S: *L. mesenteroides* NRRLB-512F(5) (SEQ ID NO: 46); ASR: *L. mesenteroides* NRRL B-1355 (6) (SEQ ID NO: 47).

FIG. 4: Alignment of 11 repeat sequences (SEQ ID NOS: 50-61) of the DSR-E enzyme and observed in the variable zone.

FIG. 5: Alignment of conserved sequences in the catalytic domain (SEQ ID NOS: 6-17 and 62-103)

Block A: essential amino acids of the N-terminal portion of the catalytic domain;

Block B: amino acids of the catalytic saccharose binding domain;

Blocks C, D, E: blocks containing three amino acid residues involved in the catalytic triad (6);

Block F: sequence containing glutamine 937 of GTF-1 studied by Monchois et al (7).

The entirely conserved amino acids are indicated in bold. ".*": conservative substitutions; ".*": semi-conservative substitutions; ---: gap. The numbering is that for SEQ ID No: 2.

FIG. 6: HPLC characterization of products synthesized by recombinant enzyme DSR-E.

6A: HPLC analysis of glucooligosaccharides obtained with dextransucrases of *L. mesenteroides* NRRL B-1299.

6B: HPLC analysis of glucooligosaccharides obtained by recombinant DSR-E. The following peaks are identified:

- 1: fructose
- 2: maltose;
- 3: sucrose;
- 4: panose;
- 5: R4;
- 6: OD4;
- 7: R5;
- 8: OD5;

A, B, C: unidentified peaks.

6C: recombinant DSR-E deleted from the catalytic domain of the carboxylic portion of the enzyme (ADSR-E).

FIG. 7: HPLC analysis of acceptor on maltose reaction products synthesized by different entire forms and deleted from the DSR-E protein.

L.m. B-1299: mixture of dextransucrases produced by *L. mesenteroides* NRRL B-1299.

The peaks were identified as follows:

- F: fructose;
M: maltose;
S: saccharose
P: panose;
R4, R5: GOS comprising $\alpha(1\rightarrow2)$ bonds;
OD4, OD5: GOS free of $\alpha(1\rightarrow2)$ bonds.

MATERIALS AND METHODS

1) Bacterial Strains, Plasmids and Growth Conditions:

All strains were kept at -80°C . in tubes containing 15% glycerol (v/v).

Leuconostoc mesenteroides B-1299 (NRRL, Peoria, USA) was cultivated at 27°C . with stirring (200 rpm) on standard medium (saccharose 40 g/l, potassium phosphate 20 g/l, yeast extract 20 g/l, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ 0.2 g/l, $\text{MnSO}_4 \cdot \text{H}_2\text{O}$ 0.01 g/l, NaCl 0.01 g/l, CaCl_2 0.02 g/l, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ 0.01 g/l), the pH being adjusted to 6.9.

Escherichia coli DH5 α and JM109 were cultivated on LB medium (Luria-Bertani).

Selection of pUC18 or pGEM-T Easy recombinant clones was carried out on LB-agar dishes supplemented with 100

12

$\mu\text{g/ml}$ of ampicillin, 0.5 mM of isopropyl- β -D-thiogalactopyranoside (IPTG) and 40 $\mu\text{g/ml}$ of 5-bromo-4-chloro-3-indolyl- β -D-galactopyranoside (X-gal). *E. coli* TOP 10 cells were used to clone the PCR TOPO Cloning (Invitrogen) product and cultivated on LB medium supplemented with kanamycin in a concentration of 50 $\mu\text{g/ml}$.

Regarding expression of *dsrE*, the ECHO Cloning System cloning kit (Invitrogen) allows a PCR product to be cloned in a donor vector (pUNI/V5-His-TOPO), preceding a step for recombination with a suitable acceptor vector (pCR-T7-E). This system requires *E. coli* PYR1, TOP 10 and PL21(DE3) pLysS cells cultivated on LB medium supplemented with 50 $\mu\text{g/ml}$ of kanamycin as well as 34 $\mu\text{g/ml}$ of chloramphenicol for the BL21(DE3)pLysS strain.

Digested and dephosphorylated pUC18 plasmids from Pharmacia (Amersham Pharmacia Biotech) were used to constitute the genomic DNA library of *L. mesenteroides* NRRL B-1299. Cloning of the PCR product necessitated the use of the pGEM-T Easy plasmid (Promega) and TOPO-XL plasmid (Invitrogen) for fragments of more than 2 kbp.

The pBAD-TOPO Thiofusion system (Invitrogen) used to construct the different deleted forms of the DSR-E protein used the *araBAD* promoter the control mechanisms for which involve the *AraC* regulatory protein. In the absence of an inducer, namely L-arabinose, the dimeric *AraC* protein associates with the regulatory structures of the operon and entrains the formation of a DNA loop, said loop then blocking transcription of genes placed under the control of the *araBAD* promoter. In the presence of L-arabinose, in contrast, *AraC* forms a complex which liberates the DNA loop and allows transcription initiation. The base expression can be limited by adding glucose to the culture medium: this reduces the level of cyclic AMP and thus concomitant activation of the CAP protein (cAMP activator protein). The level of activation obtained is a function of the concentration of L-arabinose so that the optimum conditions for production of the protein of interest can be selected with accuracy.

Further, the use of this vector can allow a 12 kDa thioredoxin tag to be positioned on the N-terminal end of the protein of interest. This fusion encourages the translation of the gene encoding said protein of interest. The tag protein can also enhance the solubility of the protein to which it is fused. The pBAD-TOPO Thiofusion system is designed to allow ready elimination of the thioredoxin tag by simple cleavage using enterokinase. Finally, using this expression system, a histidine tag is inserted on the C-terminal end side of the protein of interest. Such a tag is used to purify said protein by affinity.

Within the context of using this system, the *E. coli* TOP 10 strain was cultivated on LB medium supplemented with 100 $\mu\text{g/ml}$ of ampicillin.

2) Gel Electrophoresis, Location and Characterization of Enzyme:

After culturing *L. mesenteroides* NRRL B-1299 for 7 h, the medium was centrifuged (7000 rpm, 4°C ., 30 min) and the cells, in which 90% of the enzymatic activity was found, were concentrated 10 times in an acetate buffer solution (20 mM, pH 5.4), heated for 5 minutes at 95°C . in the presence of denaturing solution (tris HCl 62.5 mM, SDS 4%, urea 6M, bromophenol blue 0.01% and β -mercaptoethanol 200 mM). 300 μl of the mixture was deposited on 7% polyacrylamide gel. After migration, the total proteins were revealed by amido black staining, while the dextransucrase activity was detected by staining with Schiff's reagent polymer after synthesizing the dextran in situ. The bands corresponding to the active dextransucrases were excised and incubated separately in 2 ml of 20 mM sodium acetate solution, pH 5.4, containing

US 7,439,049 B2

13

100 g/l of saccharose and 50 g/l of maltose. After total consumption of saccharose, the reaction was stopped by heating to 95° C. for 5 minutes, and the reaction medium was centrifuged for 5 minutes at 15000 g to eliminate the insoluble dextran. The samples were analyzed by reverse phase chromatography (C18 column, Ultrasep 100, 6 µm, 5×300 mm, Bishoff Chromatography) using ultrapure water as the eluent, at a constant flow rate of 0.5 ml/min. The oligosaccharides were separated for 30 minutes at ambient temperature and detected by refractometry. Peptide sequencing was carried out on the selected protein bands by the Laboratoire de Microséquence, Institut Pasteur, Paris.

3) Molecular Biological Techniques Used

Purification of the *E. coli* plasmid and purification of the genomic DNA of *L. mesenteroides* was carried out using the QiaPrep Spin Plasmid kit and the Cell Culture DNA maxi kit (Qiagen) respectively. The amplification and cloning methods were carried out using standard techniques (Sambrook and Russel, 2001, supra). Restriction and modification enzymes from New England Biolabs or Gibco BRL were used in accordance with the manufacturer's instructions.

PCR was carried out with primers selected on the basis of the protein sequence obtained on an isolated band from gel electrophoresis (see supra, gel electrophoresis and enzyme localization). Two peptides were selected:

29-FYFESGK (SEQ ID NO: 18); and

24-FESQNNNP (SEQ ID NO: 19)

and used to synthesis degenerate oligonucleotides indicated in Table I below.

In this table, the numbering of which follows that of SEQ ID No: 4, it appears that the presence of a serine residue in the two peptides necessitates the synthesis of two primers for each peptide since serine can be encoded by six different codons. ECHO-dir and ECHO-inv are primers which allowed amplification of dsrE by PCR for cloning into the ECHO Cloning (Invitrogen) expression system.

14

PCR

PCR was carried out using a Perkin-Elmer thermocycler, model 2400, with 50 nanograms of genomic DNA. The quantities of primers used was 10 µM of 29-Dir-1 and of 24-Inv1. 250 µM of each triphosphate deoxynucleotide and Taq polymerase were added to the reaction mixture.

After amplification of 25 cycles at 94° C. for 30 seconds then at 50° C. for 30 seconds, then at 72° C. for 5 minutes, a 666 base pair fragment was obtained.

Certain fragments were amplified using the "Expand Long Template PCR" (Roche Boehringer Mannheim) system, in accordance with the manufacturer's instructions. This system can amplify large fragments of up to about 20 kbp highly effectively. The combination of two DNA polymerases can minimize errors during the elongation phases.

Southern Hybridization and Gene Library of *L. mesenteroides* NRRL B-1299

Chromosomal DNA from *L. mesenteroides* NRRL B-1299 was digested with different restriction enzymes then separated by electrophoresis on 0.8% agarose gel in TAE 0.5x buffer.

Genomic libraries of the bacteria were transferred onto nylon hybond N+ membranes (Amersham PharmaciaBiotech). Hybridization was carried out using the 666 base pair fragment of deoxy-adenosine-triphosphate labeled with ³²P. The labeling reaction was carried out using the "Mega Prime DNA Labelling System Kit" (Amersham PharmaciaBiotech) labeling kit, followed by purification of the probe on MicroSpin S-200HR columns. Pre-hybridization and hybridization was carried out under highly stringent conditions (65° C. overnight using the normal methods) (Sambrook and Russel, 2001, supra).

Reverse PCR

The reverse PCR reaction produces a linear DNA fragment from a circular matrix using divergent primers.

15

Genomic DNA from *L. mesenteroides* NRRL B-1299 was digested with EcoRV under the conditions recommended by the manufacturer.

After re-circularization, the digestion products were used as a matrix in a reverse PCR reaction [Extrapol II DNA polymerase (Eurobio), reaction volume of 50 µl, reverse PCR reaction parameters: 25 cycles; 94° C.; 30 seconds; 51° C., 30 seconds; 72° C., 3 minutes]. The two primers were selected as a function of the pSB2 insert sequence as indicated in FIG. 2.

FIG. 2 summarizes the conditions for obtaining different plasmids carrying *dsrE* fragments by screening the gene library and using the probes described above.

DNA Sequence and Analysis

After sequencing the peptides, degenerate primers marked out because of the frequency of use of codons in the dextranase genes of *L. mesenteroides* NRRL B-1299 were synthesized and allowed amplification of a 666 bp fragment. Sequencing this fragment revealed strong homologies with the genes of known dextranases, even though it was entirely novel.

The use of this fragment as a homologous probe in Southern experiments allowed positive signals on different tracks of genomic DNA to be marked. A first HindIII library was then screened and a recombinant plasmid termed pSB2 containing a 5.6 kbp insert was purified. An analysis of the sequence for this HindIII fragment revealed an open reading frame covering the whole insert. Then a EcoRV library was screened with a HindIII/EcoRV probe isolated at the N-terminal end of the 5.6 kbp HindIII insert. A recombinant pSB3 recombinant plasmid, tested positively by dot-blot, was shown to contain a 3.8 kbp insert which, after sequencing, was shown to contain the initiation codon for translation and the promoter region of the novel dextranase gene termed *dsrE*.

With the aim of obtaining the *dsrE* termination codon, reverse PCR was carried out on genomic DNA from *L. mesenteroides* NRRL B-1299 digested with EcoRV and religated to itself, using divergent oligonucleotide primers designated from the pSB2 insert sequence. A single fragment with the expected size of 1 kbp was amplified then cloned in pGEM-T Easy to obtain the pSB4 plasmid. After sequencing, the amplified sequence located downstream of the HindIII site comprised 221 bp and contained the reading frame termination codon for *dsrE* located 30 bp downstream of the HindIII restriction site.

Sequencing of the different fragments carried by the three plasmids was carried out on both strands by the company Genome Express. Sequence analyses of the nucleotides was carried out using "ORF Finder" (<http://www.ncbi.nlm.nih.gov/gorf/gorf.html>), Blast (<http://www.ncbi.nlm.nih.gov/blast/blast.cgi>, Altschul et al, 1997), ClustalW (<http://www2.ebi.ac.uk/clustalw>, Thompson et al, 1994), PRODOM (<http://protein.toulouse.inra.fr/prodom.html>, Corpet et al, 2000), PFAM (<http://pfam.wustl.edu/hmmsearch.shtml>, Bateman et al, 2000) and SAPS (<http://bioweb.pasteur.fr/se-gana/interfaces/saps.html>, Brendel et al, 1992), all of this software being available on the Internet.

Protein Expression

Two cloning and expression systems were used to produce recombinant proteins in *E. coli*, namely the ECHO-Cloning and pBAD-TOPO Thiofusion (Invitrogen) systems.

By way of example, the method for cloning the nucleotide sequence encoding the DSR-E protein using the ECHO-Cloning system will now be briefly described.

Two primers as proposed in Table I above were used for amplification using the "Expand Long Template" system

16

under the following conditions: 94° C. for 3 minutes, followed by 25 cycles at 94° C. for 30 seconds, 55° C. for 30 seconds, and 68° C. for 7 minutes. The PCR products were then cloned into the pUNI/V5-His-TOPO vector to obtain a donor vector (pUNI-*dsrE*) to be recombined with an acceptor vector (pCR-T7-E) and adapted for expression in *E. coli*. The final plasmid was designated pCR-T7-*dsrE*.

This construction, placing the *dsrE* gene under the control of the bacteriophage promoter T7, allowed inducible expression of the *dsrE* gene.

After induction with 1 mM of IPTG, the transformed *E. coli* BL21 cells were harvested by centrifuging after 4 hours growth and re-suspending at a final optical density of 80 at 600 nm in a 20 mM sodium acetate buffer, pH 5.4, and 1% Triton X100 (v/v) in the presence of 1 mM of PMSF to prevent proteolysis in the cell extracts after sonication.

Similar experiments carried out with the pBAD-TOPO Thiofusion system allowed the recombinant vector pBAD-TOPO-*dsrE* to be constructed.

Enzymatic Tests

The enzymatic reactions were carried out under standard conditions at 30° C. in a 20 mM sodium acetate buffer, pH 5.4, Na₂ 1 g/l and saccharose, 100 g/l. The activity of the DSR-E enzyme was determined by measuring the rate at which the reducing sugars were liberated, represented here by fructose, using the dinitrosalicylic acid method which is well known to the skilled person. One unit is defined as the quantity of enzyme which would catalyze the formation of 1 µmol of fructose per minute under standard conditions. The oligosaccharides were synthesized in a reaction medium containing 100 g/l of maltose, 200 g/l of saccharose and 0.5 units/ml of DSR-E.

As for the dextran synthesis, the enzymatic reaction was continued for 24 hours in the presence of 100 g/l of glucose. The dextran produced was precipitated in the presence of 50% (v/v) ethanol and washed twice in 50% ethanol (v/v) prior to freeze drying. It was then dissolved in an amount of 10 mg/ml in D₂O and analyzed by ¹³C NMR spectrometry.

HPLC Separation

100 µl samples were removed and heated at 95° C. for 5 minutes then diluted in ultrapure water to obtain a final concentration of total sugars of less than 5 g/l. After centrifuging, the residual substrates and the different species formed were analyzed by HPLC on a C18 column (Ultrasep 100, 6 µm, 5x300 mm, Bishoff Chromatography).

The oligosides were separated at ambient temperature for 30 minutes in ultrapure water used as the eluent, at a flow rate of 0.5 ml/min. Detection was accompanied by refractometry.

These conditions allowed the following species to be separated: fructose, maltose, leucrose, saccharose, and oligosides with a degree of polymerization that did not exceed 6.

Calculation of Yields

The method for calculating the yields for the oligoside synthesis reactions took into account the residual concentration of the acceptor in accordance with the following formula:

$$R = \frac{[GOS]_{final} - [initial\ GOS]}{[GOS]_{consumed} + [acceptor\ consumed]}$$

in which R represents the real yield of the total GOS synthesis reaction, the concentrations being expressed in g/l.

Construction of Different Deleted Forms of DSR-E Protein

The different deleted forms of the DSR-E protein [FIG. 1c) to 1i)] were obtained by PCR amplification of fragments corresponding to the *dsrE* gene then cloning in the pBAD-TOPO Thiofusion vector described above. The primers used

US 7,439,049 B2

17

for amplification of the regions selected from the *dsrE* gene are shown in Table II below. The positions of the primers are shown with respect to SEQ ID No: 5, relating to the sequence for the *dsrE* gene. The bases mutated to introduce the NcoI restriction site are shown in bold and the resulting NcoI site is underlined.

TABLE 2

SEQ ID NOS: 28-34		
Designation	Positions	Sequence 5'-3'
pBAD-PS/ ZV-dir	344-373	<u>GCCATGGCAAATACGATTGCAGTTGACAG</u>
pBAD-ZV/ CD1-dir	971-1001	<u>GCCATGGACGGTAAACCTATTTCTTGACG</u>
pBAD-CD1/ GBD-dir	3656-3682	<u>TCCATGGGTGAAAAACAAGCACCGGC</u>
pBAD-GBD/ CD2-dir	6167-6189	<u>ACCATGGATATGCTACTAATGC</u>
pBAD-CD1/ GBD-inv	3638-3658	TAACGTGTTAGGCAAGAAATCC
pBAD-GBD/ CD2-inv	6146-6172	TAATGTATTAGTGAATAAGTATTACCC
pBAD-ent- inv	8714-8737	AATTTGAGGTAATGTTGATTATC

The above direct and reverse primers were designed to ensure translational fusion of the N-terminal thioredoxin tag and the C-terminal polyhistidine tag of the truncated protein forms, satisfying the open reading frames for the regions encoding said forms.

If the pBAD-TOPO Thiofusion plasmid contains a specific restriction site for the NcoI enzyme located at the 5' end of the region encoding thioredoxin, a second NcoI site is introduced into each direct primer to enable extraction of that region if required.

The PCR amplification reactions were carried out using the "Expand Long Template" system under the following conditions: pre-denaturing at 94° C. for 3 minutes followed by 25 cycles at 94° C. for 30 seconds, 52° C. for 30 seconds and 68° C. for 7 minutes.

The amplification products generated were then cloned into the pBAD-TOPO Thiofusion vector for subsequent transformation of the *E. coli* TOP 10 strain. Recombinant clones were selected, their restriction profile analyzed to identify a recombinant plasmid carrying the insertion orientated as expected for each of the investigated forms.

EXAMPLE 1

Characterization and Purification of the DSR-E Enzyme and Obtaining the *dsrE* Gene

The enzymes produced by *L. mesenteroides* cultures and obtained on a polyacrylamide gel in SDS as described in the Materials and Methods section were isolated by cutting the gel.

The GOSs produced by the isolated enzymes were analyzed by HPLC using the methods described in (1). The enzyme the activity of which was being investigated was deduced from the nature of the GOSs produced. After trypsin proteolysis and separation of the peptides produced by

18

HPLC, 2 peptides: 29-FYFESGK (SEQ ID NO: 18) and 24-FESQNNNP (SEQ ID NO: 19), were sequenced and used as a model for the synthesis of degenerate nucleotide primers.

The different amplification and cloning steps are shown in FIG. 2. The complete gene was inserted into the pCR-T7-E plasmid and expressed in *E. coli*.

The production of a functional enzyme was attested by the production of GOSs the HPLC analysis of which is shown in FIG. 6b).

The size of peaks 5 and 7, representing GOSs with a $\alpha(1 \rightarrow 2)$ linkage, should in particular be noted.

EXAMPLE 2

Characterization of *dsrE* and DSR-E Sequences

2.1 Nucleotide Sequence

The nucleotide sequence of the enzyme is shown in SEQ ID No: 4. It is composed of a reading frame of 8506 nucleotides.

The nucleotide sequence for insertion into the pCR-T7-*dsrE* plasmid contained a ribosome binding site (RBS), 9 bases upstream of the ATG initiation codon and was composed of a hexanucleotide GAGGAA.

2.2 Analysis of Amino Acid Sequence

The 8506 nucleotide *dsrE* sequence encodes a 2835 amino acid protein shown in SEQ ID No: 2. The isoelectric point for this protein is 4.88 and its theoretical molecular weight is 313.2 kDa. Despite strong similarities with known dextranases, DSR-E is characterized by an original structure.

Alignment of the amino acid sequence with known glycosyltransferases and dextranases confirmed that the structure in the glycosyltransferase domain and dextranases domain was conserved, namely: a signal sequence, a variable zone, a highly conserved catalytic domain and a glucan binding domain. This structure is shown in FIG. 1a).

As indicated in FIG. 1b), a second catalytic domain forms the carboxy-terminal portion of the enzyme, as confirmed by PRODOM and Blast analysis.

With a molecular weight of 313.2 kDa, DSR-E had about twice the mean molecular weight of other glycosyltransferases and dextranases (1), which is in agreement with the presence of a second catalytic domain at the c-terminal end and also with a longer glucan binding region.

a) Analysis of Signal Sequence:

The signal sequence and the nucleotide sequence encoding the peptide signal were highly conserved if compared with other dextranases, as shown in FIG. 3. The cleavage site is located between amino acids 40 and 41.

b) Variable Domain:

Downstream of the signal peptide, DSR-E had a 207 amino acid variable domain. When it was compared with other variable glycosyltransferase domains, using a SAPS type alignment program, the presence of a 14 amino acid motif repeated 11 times was revealed, as indicated in FIG. 4.

This alanine-, threonine- and aspartic acid-rich repeat motif has never before been identified.

The role and significance of this region has never been elucidated. Different studies have shown that its deletion does not affect enzymatic activity (4). The role of the 14 amino acid repeat motif, which does not exist in other glycosyltransferases, remains to be determined, however.

c) Analysis of Catalytic Domains:

The first catalytic domain extends from amino acids 248 to 1142 (CD1) of SEQ ID No: 2, while the second is located

US 7,439,049 B2

19

between amino acids 1980 and 2836 (CD2). These two domains have 45% identity and 65% similarity between them.

CD1 and CD2 contain amino acids already identified in glycosyltransferases and dextranases as being essential to their enzymatic activity, as shown in FIG. 5.

The catalytic triads of CD1 and CD2 determined by analogy with α amylase (7) are present in the following positions: (Asp 527/Glu 565/Asp 638 for CD1 and Asp 2210/Glu 2248/Asp 2322 for CD2).

Other conserved residues were identified as being important for enzymatic activity: the residues Trp 425/Glu 430 for CD1 and Trp 2122/Glu 2127 for CD2, which are analogous to those of the N-terminal domain of GFT1 described by Monchois et al (4): Trp 344/Glu 349.

In contrast, certain sequences located in the conserved region of the glycosyltransferases and dextranases are not found in the CD2 of DSR-E. Thus, as indicated in FIG. 5 below, the sequences FHNDT (SEQ ID NO: 35) (2214-2220) and KGVQEKV (SEQ ID NO: 36) (2323-2329) diverge from other consensus sequences of dextranases already studied, which are respectively NVDADLL (SEQ ID NO: 37) and SEVQTVI (SEQ ID NO: 38).

d) Glucan Binding Domain:

When the DSR-E sequence is compared with known sequences, it appears that the glucan binding region is substantially longer. In fact, the length of this domain is about 500 amino acids in the glycosyltransferases and dextranases being studied while in DSR-E, it represents 836 amino acids. Several A and C repeat motifs, in particular a series of AC repetitions, have been identified. Table III below shows the consensus sequences of the repeat motifs of GBD, in particular the A and C motifs, described in the literature relating to dextranases of *Leuconostoc* and *Streptococcus* spp.

TABLE 3

SEQ ID NOS: 39-43

x: any amino acid

EXAMPLE 3

Expression of *dsrE* in *E. coli*

E. coli BL21 (DE3) pLysS pCR-T7-*dsrE* cells were cultivated as described above. After polyacrylamide gel electrophoresis (page-SDS), analysis of the protein extracts effectively revealed the presence of several bands having saccharase dextran activity, said activity being measured as described above.

The *E. coli* JM109 [pCR-T7-*dsrD*] line was deposited at the CNCM on 15th Mar. 2001 with accession number I-2649.

20

Identification and Characterization of Enzymatic Activity

Using a glucose acceptor molecule, the dextranases produced by recombinant *E. coli* were compared with those produced by *L. mesenteroides* NRRL B-1299.

HPLC analysis of the reaction products with recombinant DSR-E (FIG. 6) showed retention times corresponding to the previously identified GOSs R4 and R5 (2). Type R oligosaccharides are linear GOS series, the $\alpha(1 \rightarrow 2)$ bond being linked to the non-reducing end. The OD series, linear GOSs resulting from glycoside $\alpha(1 \rightarrow 6)$ bonds with a maltose residue at the reducing end was observed in very small quantities. Three novel compounds, in contrast, were detected in the recombinant enzyme products.

Identification of GOSs Produced:

Finally, FIG. 6b clearly shows that peaks 5 and 7 representing the GOSs of the R series are relatively larger with the recombinant enzyme than with the native enzyme in which the peaks corresponding to panose and OD5 are larger.

EXAMPLE 4

Effect of Deletion of CD2 on the Enzymatic Activity of DSR-E

The genomic DNA of *L. mesenteroides* NRRL B-1299 was used as a matrix to amplify the *dsrE* gene by PCR deleted from the sequence corresponding to the second catalytic domain. To this end, 2 oligonucleotides, ECHO-dir (5'-AGT-TGTATGAGAGACATGAGGGTAATTTGT-GACCGTAAAAAATTG) (SEQ ID NO: 48) corresponding to the nucleotide sequence -6 to 39 and containing the translation initiation codon, and ECHO-inv-del (5'-GTATTAGT-GAATAAGTATTCACCATTCGATT-TATCGTCAAAATAGTACG) (SEQ ID NO: 49) complementary to the sequence 5889-5937 and corresponding to the peptide sequence YYFDDKNGEYCFINT (SEQ

ID NO: 44), were synthesized, to fuse the C-terminal end of the deleted protein with a His tag present on the cloning vector. The PCR reaction was carried out using a DNA thermal cycler model 2400 (Perkin Elmer) with the Expand Long Template System (Boehringer Mannheim) using the following temperature cycle: 94° C. for 3 min, then 25 cycles with: 30 s at 94° C., 30 s at 55° C. and 7 min at 68° C. The PCR product was then cloned into the pUNI donor vector and the resulting plasmid was used in a recombination reaction with the pCR-T7-*dsrE* expression vector.

The cell extract, preparation, enzymatic reaction and reaction product analysis were those described in Example 3 above.

US 7,439,049 B2

21

The HPLC profile of the GOSs obtained with the DSR-E enzyme deleted from the CD2 domain appear in FIG. 6c).

The type R GOS shown as peaks 5 and 7 shown in FIGS. 6a) and 6b) are entirely absent from the products obtained with the recombinant enzyme deleted from CD2. The only analyzable products were those corresponding to linear oligosides resulting from $\alpha(1\rightarrow6)$ bonds with a maltose residue in the reducing portion. This result clearly indicates the essential role of the catalytic domain located in the carboxy-terminal portion of the enzyme in its capacity to form $\alpha(1\rightarrow2)$ osidic bonds.

EXAMPLE 5

Study of Structure-function Relationships of DSR-E Protein

The *dsrE* gene, insofar as it is the first gene encoding a dextranucrase catalyzing the synthesis of $\alpha(1\rightarrow2)$ bonds to have been cloned, is of particular interest. Thus, it is important to characterize this gene and its expression product, in this case by determining the roles of the different domains making up the DSR-E protein in the function which has been assigned thereto, namely to correspond to a $\alpha(1\rightarrow2)$ specific to the synthesis of $\alpha(1\rightarrow2)$ bonds.

5.1 Deleted forms of DSR-E Protein:

A study of six different forms obtained by deletion of one or more domains from the DSR-E protein was envisaged in order to determine the following by reference to FIG. 1 below: (i) the influence of the presence of the CD2 domain by studying GBD-CD2 and Δ (CD2) constructions; (ii) the influence of the presence of the variable zone by analyzing the Δ (ZV) and CD1-GBD forms; and (iii) the intrinsic catalytic potential of the CD1 and CD2 domains expressed in an isolated manner (CD1 and CD2 constructions).

The catalytic activity of each of the different forms was compared with that observed with the control corresponding to the entire form deleted from the single signal peptide Δ (PS) [FIG. 1c)].

5.2 Analysis of Constructions:

At the end of the experimental PCR amplification and cloning procedure detailed above, several clones with an insertion in the expected orientation were obtained for each of the envisaged constructions, with the exception of the truncated GBD-CD2 form for which the desired amplification product could not be cloned.

The sequences for the insertions were determined in order to ensure the absence of mutations that after translation may modify the amino acids located at positions presumed essential for the enzymatic activity of the protein encoded this way.

A mutation was identified at the 31st insertion base relative to the control Δ (PS), inducing substitution of one aspartic acid by an asparagine in position 10 of the variable zone. As it is not located in the repeat motifs S of the variable zone (FIG. 4), it appears that the incidence of this mutation on the finally observed function is negligible.

A mutation was introduced into the amplification product corresponding to the construction Δ (CD2), modifying the aromatic residue F1411 in leucine. This mutation was located in the first third of the glucan binding domain GBD at a junction between two repeat motifs.

Because of the errors made by polymerase during PCR amplification, the construction Δ (ZV) did not have the expected sequence. In fact, the insertion contained an open reading frame, that frame essentially corresponding to the GBD-CD2 form which could not be cloned. However, in the GBD-CD2 form obtained definitively in place of Δ (ZV), 46

22

N-terminal residues were absent. Now, the GBD domain has more than 800 amino acids forming a concatenation of 24 repeat units. This concatenation is such that, over the 46 truncated residues, only the last 9 were located at one of said units, in particular at the first thereof. It thus appears plausible to consider that deletion of these amino acids has no influence on the enzymatic reaction catalyzed by the corresponding protein form. This hypothesis supported by the fact that in other dextranucrases, the loss of a certain number of repeat units from the GBD domain does not significantly reduce the activity of the resulting protein.

The insertion encoding the CD1-GBD form contained a mutation affecting the F633 residue located in the CD1 domain and more precisely in the region that is highly conserved in dextranucrases, itself located just in front of the second aspartic acid of the catalytic triad (FIG. 5). The expected phenylalanine was substituted by a leucine. It is difficult at this stage to estimate the impact of such a mutation on the observed catalytic activity.

The sequence of insertions encoding the catalytic domains CD1 and CD2 was determined in the same manner as for the other constructions.

5.3 Expression Products and Enzymatic Activities

The proteins corresponding to the various deleted forms of DSR-E were expressed by subjecting the recombinant *E. coli* cells to induction by L-arabinose in a concentration of 0.002%. The enzymatic activity was observed for the first four hours following induction.

The protein extracts obtained by sonication of the cell residues were analyzed by SDS-PAGE electrophoresis (Sambrook and Russel, 2001, supra). The molecular masses of the recombinant proteins were estimated from the electrophoretic profiles obtained, said masses essentially corresponding to the expected masses taking into account the 12 kDa incrementation linked to the thioredoxin tag. Table IV below summarizes the estimated values for the molecular masses of the different truncated forms and, by way of comparison, provides the expected masses.

TABLE IV

Protein form	Expected mass (kDa)	Expected mass + thioredoxin (kDa)	Estimated mass (kDa)
Δ (PS)	309	321	324
Δ (CD2)	218	230	ND
GBD-CD2	224	/	233
CD1-GBD	193	205	199
CD1	99	111	111
CD2	95	107	ND

ND: not determined

Table V below indicates the nature and position of amino acids marking the start and end of the protein forms constructed in this study. The different positions refer to SEQ ID No: 2 corresponding to the protein DSR-E.

TABLE V

Protein form	Starting amino acid	Ending amino acid	Total length
Δ (PS)	N41	I2835	2795
Δ (CD2)	M1	L1980	1980
GBD-CD2	M1188	I2835	1648
CD1-GBD	I248	L1980	1733
CD1	I248	Q1141	894
CD2	D1981	I2835	855

The GBD-CD2 form did not have a thioredoxin tag. In fact, this form was derived from experimental uncertainty occa-

US 7,439,049 B2

23

sioned by the procedure for PCR amplification of the sequence assumed to encode the $\Delta(ZV)$ form. Because of the deletions from the sequences thus generated, the thioredoxin tag, in principle situated at 5' from the protein of interest, could not be fused with the GBD-CD2 region.

The quality of the electrophoresis gels did not allow determination as to whether the level of expression of the different forms was quantitatively identical and as a result whether said forms were present in the same proportions in the cell extracts.

The activity measurements provided were established on the basis of a given volume of cell extracts but could not be extrapolated to the quantity of each protein actually contained in said volume of extracts.

The synthesis of dextran polymers *in situ* by incubating electrophoresis gels in a saccharose solution and subsequent staining with Schiff's reagent confirmed the presence of proteins having a glucan-saccharase activity in cell extracts corresponding to $\Delta(PS)$, $\Delta(CD2)$, GBD-CD2 and CD1-GBD.

Table VI below shows the maximum enzymatic activities observed for each construction. The results confirm the data drawn from the experiments in which the gels were stained with Schiff's reagent, namely the fact that the cell extracts relative to the forms $\Delta(PS)$, $\Delta(CD2)$, GBD-CD2 and CD1-GBD had a saccharase activity, in contrast to the two catalytic domains taken in isolation. This result was in agreement with the literature, given that it has been demonstrated that in other dextranases, the absence of the GBD domain induced a drastic loss of enzymatic activity (8, 9, 10).

TABLE VI

Protein form	$\Delta(PS)$	$\Delta(CD2)$	GBD-CD2	CD1-GBD	CD1	CD2
maximum activity (U/l)	1063	181	86	235	5.3	0

The intrinsic activity of the CD1 form was too low to be detected. Regarding the GBD-CD2 form, it had a non negligible activity which leads to the conclusion that the corresponding structural organization, namely a catalytic domain downstream of the glucan binding domain, remains enzymatically active.

5.4 Effect of Deletions on Oligoside Synthesis:

Provided that the specificity of the synthesis of $\alpha(1\rightarrow2)$ bonds was conserved during the reaction in the presence of an acceptor, experiments for synthesizing oligosides starting from maltose were carried out (FIG. 7).

When the reactions were carried out to completion, i.e. all of the saccharose had been consumed, the oligoside synthesis yields were calculated. The results are shown in Table VII below. Only the reaction involving the cell extract containing the protein form CD1 did not allow such a calculation. The temperature effect probably resulted in inactivation of the very low activity present in the protein extract.

TABLE VII

Protein form	Yield of oligosides in OD series (%)	Yield of oligosides in R series (%)	Total oligoside yield
Native enzyme	36	28	64
$\Delta(PS)$	41	14	55
$\Delta(CD2)$	67	1	68
GBD-CD2	45	47	92
CD1-GBD	100	0	100

24

As indicated in FIG. 7 below, the presence of oligosides from series R was only detected with enzymatic forms having the catalytic domain CD2, with the exception of the case in which said domain was isolated and then rendered completely inactive. In fact, the retention time for the oligosides synthesized by the deleted form of the second catalytic domain and by the CD1-GBD form corresponded only to those in the OD series, i.e. to GOSs deprived of $\alpha(1\rightarrow2)$ bonds. These results thus indicate that the CD2 domain was required for the formation of $\alpha(1\rightarrow2)$ bonds.

The products obtained with the GBD-CD2 form have supported these observations. This construction, which had CD2 as the only catalytic domain, was capable of catalyzing in a preponderant manner the synthesis of oligosides from the R series, having $\alpha(1\rightarrow2)$ bonds. Thus, this results demonstrates that specificity in terms of the function of the DSR-E enzyme resides in the highly original sequence for this domain, and not in the association of two catalytic domains. Further, the GBD-CD2 protein form also allowed the synthesis of $\alpha(1\rightarrow6)$ bonds. However, the low yields obtained for these oligosides indicated that they were preferentially converted into oligosides with a higher degree of polymerization belonging to the R series, which prevented their accumulation in the reaction medium, differing from molecules from the R series which were not converted (2).

By comparing the profiles of the products obtained as shown in FIG. 7, it is clear that the entire form $\Delta(PS)$ mainly synthesizes linear oligosides. In fact, the molecule R4 was absent and the oligoside R5 only present in a small amount. The catalytic domain CD1 catalyzed the exclusive synthesis of $\alpha(1\rightarrow6)$ bonds and its activity appeared to be preponderant with respect to that of the CD2 domain. In addition, in the entire form of the enzyme, the implication of the CD2 domain would thus be less important because of: (i) lower intrinsic catalytic parameters; and/or (ii) a global enzyme configuration that was unfavorable to its activity.

Further, the entire enzyme $\Delta(PS)$ catalyzed the synthesis of oligosides from the R series with a lower yield than that observed with the mixture of dextranases produced by *L. mesenteroides* NRRL B-1299 (FIG. 7). The yield obtained, 28%, was situated between those observed for the entire form $\Delta(PS)$ and for the GBD-CD2 form. It is known that the wild strain produces several forms of dextranases that are susceptible of synthesizing osidic bonds, in particular $\alpha(1\Delta2)$ bonds. One hypothesis has been proposed, in which said forms are the degradation products of DSR-E. Insofar as the truncated forms of DSR-E such as GBD-CD2 could catalyze the synthesis of oligosides from the R series more effectively, it would appear that the yields obtained with the heterogeneous mixture produced by *L. mesenteroides* NRRL B-1299 can be attributed to the contribution of the catalytic activities of the ensemble of said different enzymatic forms.

In conclusion, by isolating a particular dextranase produced by *L. mesenteroides*, the inventors have succeeded in characterizing a particular and unexpected structure of this enzyme that can produce oligosides of interest and have $\alpha(1\rightarrow2)$ type linkages. Identification and characterization of this sequence allows the construction of recombinant cells or organisms specifically expressing this enzyme and also allows its modification by directed or random mutagenesis or by DNA shuffling to further improve its characteristics to be envisaged.

This invention can also improve the yield and reproducibility of the production of GOSs of interest for the different applications cited above.

What is claimed is:

1. An isolated nucleic acid comprising SEQ ID NO:4 or its full length complementary strand.

2. An isolated nucleic acid comprising:

a) sequence encoding a dextranucrase expressed by the plasmid pCR-Ty-dsrD deposited at the CNCM with accession number I-2649; or

b) a full length complementary sequence to the sequence in a).

3. An expression vector comprising a nucleic acid according to claim 1 or claim 2.

4. The expression vector according to claim 3, in which the nucleic acid is under the control of a sequence allowing its expression in prokaryotic or eukaryotic cells.

5. A host cell transformed by a nucleic acid according to claim 1.

6. A host cell transformed by a vector according to claim 3.

7. The transformed host cell according to claim 5, selected from the group comprising *E. coli*, *Leuconostoc*, plants, *Lactococci* and *Bacilli* or yeasts.

8. The transformed host cell according to claim 7, wherein said transformed host cell is a strain of *E. coli* deposited at the CNCM with accession number I-2649.

9. An isolated nucleic acid encoding an enzyme with glycosyltransferase activity that can form dextrans having $\alpha(1\rightarrow2)$ linkages from saccharose, α -D-fluoroglucose, paranitrophenyl- α -D glucopyranoside, α -D-glucopyranoside- α -D sorbofuranoside or 4-O- α -D galactopyranosylsucrose and comprising at least one nucleotide sequence encoding a catalytic domain of SEQ ID NO:3 and located 3' of a sequence encoding a glucan binding domain.

10. An isolated nucleic acid consisting of SEQ ID NO:4 or its full length complementary strand.

11. A host cell transformed by a nucleic acid according to claim 9.

12. A host cell transformed by a nucleic acid according to claim 2.

13. A host cell transformed by an expression vector according to claim 4.

14. The isolated nucleic acid molecule according to claim 9, wherein the nucleotide sequence encoding the glucan binding domain is between two nucleotide sequences encoding the catalytic domains.

* * * * *

specified in paragraph (1) overlap, the period of any adjustment granted under this subsection shall not exceed the actual number of days the issuance of the patent was delayed." 35 U.S.C.

§ 154(b)(2)(A). Plaintiffs claim that the PTO has misconstrued or misapplied this provision, and that the PTO is denying them a portion of the term Congress has provided for the protection of their intellectual property rights.

Statutory Scheme

Until 1994, patent terms were 17 years from the date of issuance. See 35 U.S.C. § 154 (1992) ("Every patent shall contain . . . a grant . . . for the term of seventeen years . . . of the right to exclude others from making, using, or selling the invention throughout the United States. . . ."). In 1994, in order to comply with treaty obligations under the General Agreement on Tariffs and Trade (GATT), the statute was amended to provide a 20-year term from the date on which the application is first filed. See Pub. L. No. 103-465, § 532, 108 Stat. 4809, 4984 (1994). In 1999, concerned that extended prosecution delays could deny inventors substantial portions of their effective patent terms under the new regime, Congress enacted the American Inventors Protection Act, a portion of which -- referred to as the Patent Term Guarantee Act of 1999 -- provided for the adjustments that are at issue in this case. Pub. L. No. 106-113, §§ 4401-4402, 113 Stat. 1501, 1501A-557 (1999).

As currently codified, 35 U.S.C. § 154(b) provides three guarantees of patent term, two of which are at issue here. The first is found in subsection (b) (1) (A), the "[g]uarantee of prompt Patent and Trademark Office response." It provides a one-day extension of patent term for every day that issuance of a patent is delayed by a failure of the PTO to comply with various enumerated statutory deadlines: fourteen months for a first office action; four months to respond to a reply; four months to issue a patent after the fee is paid; and the like. See 35 U.S.C. § 154(b) (1) (A) (i)-(iv). Periods of delay that fit under this provision are called "A delays" or "A periods." The second provision is the "[g]uarantee of no more than 3-year application pendency." Under this provision, a one-day term extension is granted for every day greater than three years after the filing date that it takes for the patent to issue, regardless of whether the delay is the fault of the PTO.¹ See 35 U.S.C. § 154(b) (1) (B). The period that begins after the three-year window has closed is referred to as the "B delay" or the "B period". ("C delays," delays resulting from interferences, secrecy orders, and appeals, are similarly treated but were not involved in the patent applications underlying this suit.)

¹ Certain reasons for exceeding the three-year pendency period are excluded, see 35 U.S.C. § 154(b) (1) (b) (i)-(iii), as are periods attributable to the applicant's own delay. See 35 U.S.C. § 154(b) (2) (C).

The extensions granted for A, B, and C delays are subject to the following limitation:

(A) In general.--To the extent that periods of delay attributable to grounds specified in paragraph (1) overlap, the period of any adjustment granted under this subsection shall not exceed the actual number of days the issuance of the patent was delayed.

35 U.S.C. § 154(b)(2)(A). This provision is manifestly intended to prevent double-counting of periods of delay, but understanding that intent does not answer the question of what is double-counting and what is not. Proper interpretation of this proscription against windfall extensions requires an assessment of what it means for "periods of delay" to "overlap."

The PTO, pursuant to its power under 35 U.S.C. § 154(b)(3)(A) to "prescribe regulations establishing procedures for the application for and determination of patent term adjustments," has issued final rules and an "explanation" of the rules, setting forth its authoritative construction of the double-counting provision. The rules that the PTO has promulgated essentially parrot the statutory text, see 37 C.F.R. § 1.703(f), and so the real interpretive act is found in something the PTO calls its Explanation of 37 CFR 1.703(f) and of the United States Patent and Trademark Office Interpretation of 35 U.S.C. § 154(b)(2)(A), which was published on June 21, 2004, at 69 Fed. Reg. 34238. Here, the PTO "explained" that:

the Office has consistently taken the position that if an application is entitled to an adjustment under the three-year pendency provision of 35 U.S.C. § 154(b) (1) (B), the entire period during which the application was pending before the Office (except for periods excluded under 35 U.S.C. § 154(b) (1) (B) (i)-(iii)), and not just the period beginning three years after the actual filing date of the application, is the relevant period under 35 U.S.C. § 154(b) (1) (B) in determining whether periods of delay "overlap" under 35 U.S.C. 154(b) (2) (A).

69 Fed. Reg. 34238 (2004) (emphasis added). In short, the PTO's view is that any administrative delay under § 154(b) (1) (A) overlaps any 3-year maximum pendency delay under § 154(b) (1) (B): the applicant gets credit for "A delay" or for "B delay," whichever is larger, but never A + B.

In the plaintiffs' submission, this interpretation does not square with the language of the statute. They argue that the "A period" and "B period" overlap only if they occur on the same calendar day or days. Consider this example, proffered by plaintiff: A patent application is filed on 1/1/02. The patent issues on 1/1/08, six years later. In that six-year period are two "A periods," each one year long: (1) the 14-month deadline for first office action is 3/1/03, but the first office action does not occur until 3/1/04, one year late; (2) the 4-month deadline for patent issuance after payment of the issuance fee is

1/1/07, but the patent does not issue until 1/1/08, another year of delay attributable to the PTO. According to plaintiff, the "B period" begins running on 1/1/05, three years after the patent application was filed, and ends three years later, with the issuance of the patent on 1/1/08. In this example, then, the first "A period" does not overlap the "B period," because it occurs in 2003-04, not in 2005-07. The second "A period," which covers 365 of the same days covered by the "B period," does overlap. Thus, in plaintiff's submission, this patent holder is entitled to four years of adjustment (one year of "A period" delay + three years of "B period" delay). But in the PTO's view, since "the entire period during which the application was pending before the office" is considered to be "B period" for purposes of identifying "overlap," the patent holder gets only three years of adjustment.

Chevron Deference

We must first decide whether the PTO's interpretation is entitled to deference under Chevron v. NRDC, 467 U.S. 837 (1984). No, the plaintiffs argue, because, under the Supreme Court's holdings in Gonzales v. Oregon, 546 U.S. 243 (2006), and United States v. Mead Corp., 533 U.S. 218 (2001), Congress has not "delegated authority to the agency generally to make rules carrying the force of law," and in any case the interpretation at issue here was not promulgated pursuant to any such authority.

See Gonzales, 546 U.S. at 255-56, citing Mead, 533 U.S. at 226-27. Since at least 1996, the Federal Circuit has held that the PTO is not afforded Chevron deference because it does not have the authority to issue substantive rules, only procedural regulations regarding the conduct of proceedings before the agency. See Merck & Co. v. Kessler, 80 F.3d 1543, 1549-50 (Fed. Cir. 1996).

Here, as in Merck, the authority of the PTO is limited to prescribing "regulations establishing procedures for the application for and determination of patent term adjustments under this subsection." 35 U.S.C. § 154(b)(3)(A) (emphasis added). Indeed, a comparison of this rulemaking authority with the authority conferred for a different purpose in the immediately preceding section of the statute makes it clear that the PTO's authority to interpret the overlap provision is quite limited. In 35 U.S.C. § 154(b)(2)(C)(iii) the PTO is given the power to "prescribe regulations establishing the circumstances that constitute a failure of an applicant to engage in reasonable efforts to conclude processing or examination of an application" (emphasis added) -- that is, the power to elaborate on the meaning of a particular statutory term. No such power is granted under § 154(b)(3)(A). Chevron deference does not apply to the interpretation at issue here.

Statutory Construction

Chevron would not save the PTO's interpretation, however, because it cannot be reconciled with the plain text of the statute. If the statutory text is not ambiguous enough to permit the construction that the agency urges, that construction fails at Chevron's "step one," without regard to whether it is a reasonable attempt to reach a result that Congress might have intended. See, e.g., MCI v. AT&T, 512 U.S. 218, 229 (1994) ("[A]n agency's interpretation of a statute is not entitled to deference when it goes beyond the meaning that the statute can bear.").

The operative question under 35 U.S.C. § 154(b) (2) (A) is whether "periods of delay attributable to grounds specified in paragraph (1) overlap." The only way that periods of time can "overlap" is if they occur on the same day. If an "A delay" occurs on one calendar day and a "B delay" occurs on another, they do not overlap, and § 154(b) (2) (A) does not limit the extension to one day. Recognizing this, the PTO defends its interpretation as essentially running the "period of delay" under subsection (B) from the filing date of the patent application, such that a period of "B delay" always overlaps with any periods of "A delay" for the purposes of applying § 154(b) (2) (A).

The problem with the PTO's construction is that it considers the application delayed under § 154(b) (1) (B) during the

period before it has been delayed. That construction cannot be squared with the language of § 154(b)(1)(B), which applies "if the issue of an original patent is delayed due to the failure of the United States Patent and Trademark Office to issue a patent within 3 years." (Emphasis added.) "B delay" begins when the PTO has failed to issue a patent within three years, not before.

The PTO's interpretation appears to be driven by Congress's admonition that any term extension "not exceed the actual number of days the issuance of the patent was delayed," and by the PTO's view that "A delays" during the first three years of an applications' pendency inevitably lead to "B delays" in later years. Thus, as the PTO sees it, if plaintiffs' construction is adopted, one cause of delay will be counted twice: once because the PTO has failed to meet and administrative deadline, and again because that failure has pushed back the entire processing of the application into the "B period." Indeed, in the example set forth above, plaintiffs' calendar-day construction does result in a total effective patent term of 18 years under the (B) guarantee, so that -- again from the PTO's viewpoint -- the applicant is not "compensated" for the PTO's administrative delay, he is benefitted by it.

But if subsection (B) had been intended to guarantee a 17-year patent term and no more, it could easily have been written that way. It is true that the legislative context -- as

distinct from the legislative history -- suggests that Congress may have intended to use subsection (B) to guarantee the 17-year term provided before GATT. But it chose to write a "[g]uarantee of no more than 3-year application pendency," 35 U.S.C.

§ 154(b)(1)(B), not merely a guarantee of 17 effective years of patent term, and do so using language separating that guarantee from a different promise of prompt administration in subsection (A). The PTO's efforts to prevent windfall extensions may be reasonable -- they may even be consistent with Congress's intent -- but its interpretation must square with Congress's words. If the outcome commanded by that text is an unintended result, the problem is for Congress to remedy, not the agency.

 Defendant. :

ORDER

For the reasons stated in the accompanying memorandum opinion, plaintiffs' motion for summary judgment [12] is **GRANTED** and defendant's motion for summary judgment [16] is **DENIED**. The case is remanded to the agency for further proceedings that are consistent with this opinion.
